⁶ Summary

⁷ PixelMap is a browser-based application for creating custom channel maps for Neuropixels ⁸ probes that respects electrode wiring constraints. Neuropixels probes, widely used for high- ⁹ density neural recordings, possess more physical electrodes than can be used for simultaneous ¹⁰ recording because they contain fewer analogue-to-digital converters (ADCs) than data lines. ¹¹ Each ADC is hard-wired to several electrodes, creating complex interdependencies where ¹² selecting one electrode makes others unavailable. PixelMap provides an installation-free, ¹³ browser-based interface for researchers to design arbitrary recording configurations that meet ¹⁴ their experimental requirement while satisfying these hardware constraints. The tool generates ¹⁵ IMRO (IMEC Read Out) files compatible with SpikeGLX, the most common data acquisition ¹⁶ software for Neuropixels recordings.

Statement of need

¹⁷ Neuropixels probes have revolutionised systems neuroscience by enabling simultaneous recordings from hundreds of neurons at spike resolution across multiple brain regions at any depth ¹⁸ ([Beau et al., 2021, 2025; Bondy et al., 2024; Jun et al., 2017; Steinmetz et al., 2021; Ye et al., 2025](#)). However, configuring these probes for successful recording of neural data presents challenges. Neuropixels probes fit 960 to 5120 electrodes but can only record from 384 or 1536 ²⁰ channels simultaneously (Table 1), limited by the number of integrated analogue-to-digital ²¹ converters (ADCs). The electrode-to-ADC wiring map follows complex patterns that vary with ²² each Neuropixels version, making manual channel selection error-prone and time-consuming. ²³

²⁴ While existing tools like SpikeGLX and Open Ephys provide tools to edit channelmap as .imro ²⁵ files, they require desktop apps, lack user-friendliness, and do not allow selection of fully ²⁶ arbitrary electrode geometries. Researchers often need custom channel configurations to target ²⁷ specific brain regions or optimise spatial sampling, but creating these configurations manually ²⁸ requires a deep understanding of the probe's wiring architecture and careful verification to ²⁹ avoid wiring violations. ³⁰

³¹ PixelMap addresses these needs by:

- ³² **1. Being available on any machine installation-free:** The tool is available as a web application at <https://pixelmap.pni.princeton.edu> but can also be installed locally as a Python package.
- ³³ **2. Visualising wiring constraints interactively:** When users select electrodes, the interface immediately shows which other electrodes become unavailable (marked in black) due to shared ADC lines, preventing invalid configurations.
- ³⁴ **3. Supporting arbitrary electrode geometries:** Users can select electrodes through (i) picking from presets for common geometries, (ii) textually typing electrode ranges,

41 enabling repeatable selection, (iii) dragging selection boxes and clicking on the probe
 42 visualisation itself, and (iv) loading pre-existing .imro files. These four selection methods
 43 are intercompatible so can be used together. For instance, a SpikeGLX .imro file can be
 44 loaded as a starting point, and selection boxes used to further refine the channelmap
 45 geometry.

Probe Version	Physical Channels	Simultaneously Recordable Channels
Neuropixels 1.0	960	384
Neuropixels 2.0 (single shank)	1,280	384
Neuropixels 2.0 (4-shank)	5,120 (1,280 per shank)	384
Neuropixels 2.0 Quad Base	5,120 (1,280 per shank)	1,536

46 **Table 1: Number of physical and simultaneously addressable electrodes across Neuropixels**
 47 **probe versions.**

48 Implementation

49 The Channelmap Generator is implemented in Python using Holoviz' Panel (Yang et al., 2022)
 50 for the web interface, providing an interactive and responsive user experience. The software
 51 architecture consists of three main components.

52 First, the **wiring maps** at ./wiring_maps/*.csv are custom CSV files describing the electrode-
 53 to-ADC mappings for each supported probe type. They were built from files provided by IMEC
 54 (Neuropixels manufacturer).

55 Second, the **core logic** at ./backend.py implements the constraint-checking algorithms that
 56 validate electrode selections against probe-specific wiring maps. This handles the complex
 57 mapping between physical electrodes and ADC channels for different probe types (Neuropixels
 58 1.0, 2.0 single-shank, and 2.0 four-shank so far). Hash tables (Python dictionaries) are used to
 59 query incompatible electrode pairs with O(1) complexity and improve performance.

60 Finally, the **graphical user interface** at ./gui/gui.py was built with Holoviz' Panel. The
 61 interface provides real-time visualisation of the probe layout with electrode colour-coded based
 62 on their selection state (available in grey, selected in red, or unavailable in black). The
 63 interface supports the abovementioned four selection modes, including bokeh-based interactive
 64 click-selection and box-selection to select or deselect electrodes. User interactions trigger
 65 immediate recalculation of available electrodes based on the current selection state. This
 66 design ensures users receive instant feedback about constraint violations, preventing invalid
 67 configurations before file generation.

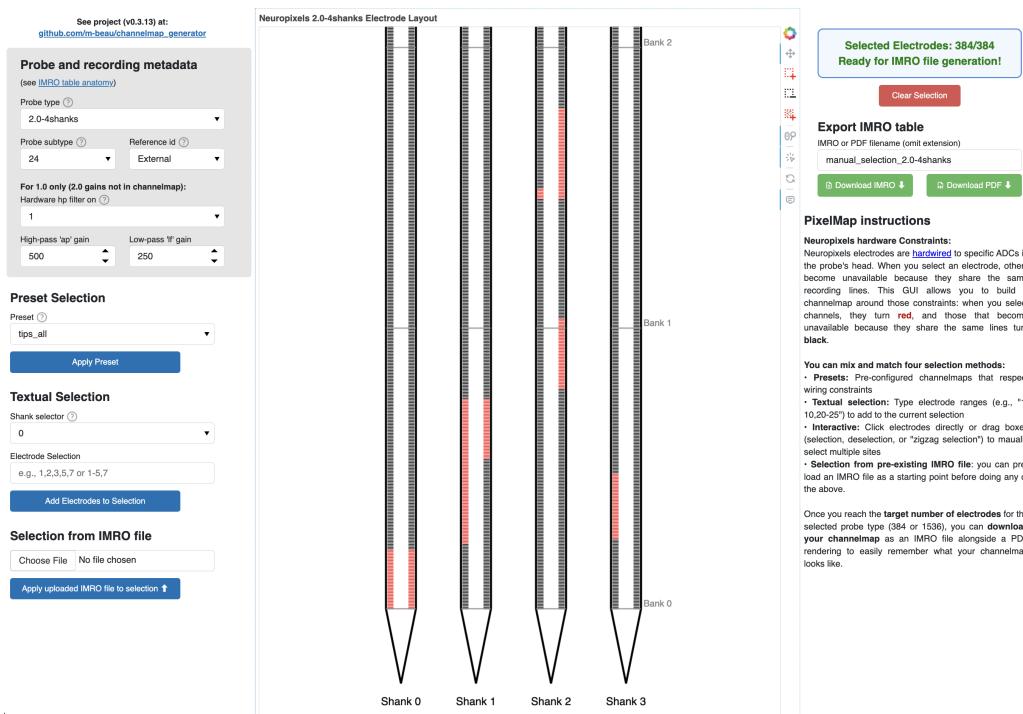

Figure 1: PixelMap's browser-based graphical user interface.

Center: Main panel featuring the probe's physical layout with one or four shanks that exhibit the 960/shank (1.0) or 1280/shank (2.0) physical electrodes to be selected. Electrodes available for selection are light grey, selected electrodes turn red, and electrodes that become unavailable due to hardware wiring constraints turn black. In this example, 384 electrodes have been selected (matching the maximum simultaneous recording capacity), with a distributed pattern across multiple banks, illustrating that PixelMap allows selection of arbitrary channelmap geometries.

Left: panel to input probe metadata (also part of .imro files) as well as three methods of electrode selection: preset geometries, manual textual input of electrode ranges, and pre-loading an existing .imro file. These three methods of electrode selection can be mixed together with an interactive click-and-drag box selector and deselector.

Right: electrode status indicator that turns green to confirm the selection is complete and is ready for IMRO file generation. Users can export their configuration via the “Download IMRO” button for direct use in SpikeGLX or save a PDF visualization to easily remember the geometry of the corresponding .imro file in the future. Below the status indicator are PixelMap’s instructions.

68 Installation and Usage

69 PixelMap can be used through:

- 70 1. **Web application:** Available at <https://pixelmap.pni.princeton.edu> for immediate use without installation.
- 71 2. **Local installation:** Via pip (`pip install .`) or uv (`uv run cmap_gui`) from the cloned GitHub repository.
- 72 3. **Docker container:** Users can download the image used for the website and run the container locally.
- 73 4. **Programmatic API:** Python scripts can directly call `generate_imro_channelmap()` for batch processing or integration into analysis pipelines.

78 For more details, see the project repository at https://github.com/m-beau/channelmap_generator.

80 The software includes an automated test suite with 41 tests covering hardware constraint validation, all preset configurations, IMRO file generation for all supported probe types, and

82 end-to-end workflows. Tests run automatically via GitHub Actions continuous integration
 83 on every code change, ensuring software reliability. See the repository's tests/ directory for
 84 details.
